

# CLINICAL PROFILE OF PEDIATRIC ONSET VS ADULT-ONSET MULTIPLE SCLEROSIS

Sameh Saed, Jaidaa Mekky, Hany Eldeeb, Fatma Alkolfat

Department of Neurology and Psychiatry , Faculty of Medicine, Alexandria University.

## Introduction

MS is an immune-mediated, chronic disease of the central nervous system that affects mainly the adults. However, it is increasingly recognized that MS may start in the childhood resulting in a relentlessly progressive disability and cognitive impairment. When the age of MS patients at disease onset is younger than 18 years, Pediatric-onset MS (POMS) is defined. Registries across the globe are reporting inconstant data about their POMS patients. Therefore, there is a need for more research into the clinical characteristics of POMS in our population.

## Aim of the work

- The aims of the study are:**
- 1.To compare the clinical characteristics of patients with (POMS) to (AOMS) in a sample of Egyptian patients at Alexandria university.
  - 2.To identify predictors for disability progression in POMS.

## Subjects and Methods

This study was a cross-sectional study that included MS patients who visited the MS clinic of the neuropsychiatry department, Alexandria University from January 2019 to January 2021. We entered their epidemiological, clinical, radiological data, and CSF results from their updated records as well as follow up interviews.

## Results

POMS patients were about 9% of all the registered MS cases in the study duration.

**Table :** Comparison between POMS and AOMS groups according to clinical variables and treatment plans.

|  | POMS         | AOMS          | P                     |
|--|--------------|---------------|-----------------------|
| <b>Duration of illness (Mean ± SD)</b>                                       | 12.15 ± 6.98 | 6.72 ± 5.52   | <0.001*               |
| <b>Interval between the first two attacks (months)</b>                       | 40.0 ± 47.3  | 22.71 ± 34.3  | 0.066                 |
| <b>Recovery of 1<sup>st</sup> attack</b>                                     |              |               |                       |
| Complete   | 88.5%        | 71.7%         | 0.068                 |
| Partial  | 11.5%        | 28.3%         |                       |
| <b>The relapse rate in the 1<sup>st</sup> yearMean ± SD.</b>                 | 1.27 ± 0.67  | 1.49 ± 0.83   | 0.123                 |
| <b>No. of relapses in the 1<sup>st</sup> 5 yearsMean ± SD.</b>               | 3.75 ± 3.58  | 4.41 ± 3.63   | 0.091                 |
| <b>ARR in the first 5 years Mean ± SD.</b>                                   | 0.75 ± 0.72  | 0.88 ± 0.73   | 0.091                 |
| <b>Time to 1<sup>st</sup> relapseMean ± SD</b>                               | 40.0 ± 47.35 | 22.71 ± 34.33 | 0.066                 |
| <b>ARR(Mean ± SD)</b>  | 0.72 ± 0.57  | 1.04 ± 0.78   | 0.008*                |
| <b>ARR in cases with 1<sup>st</sup> relapse interval less than 60 months</b> | 0.95 ± 0.57  | 1.08 ± 0.79   | 0.512                 |
| <b>Total No. of relapses. (Mean ± SD)</b>                                    | 5.85 ± 4.73  | 5.51 ± 5.28   | 0.311                 |
| <b>No. of relapses pre-diagnosis. (Mean ± SD)</b>                            | 2.31 ± 1.44  | 2.98 ± 2.96   | 0.174                 |
| <b>Baseline EDSS at the start of DMT. (Mean ± SD)</b>                        | 1.56 ± 1.57  | 2.45 ± 1.79   | 0.012*                |
| <b>EDSS in patients with disease duration. (0 – 5 years)</b>                 | 2.75 ± 1.77  | 2.39 ± 1.66   | 0.693                 |
| <b>EDSS in patients with disease duration. (&gt;5– 10 years)</b>             | 2.50 ± 2.28  | 3.13 ± 1.98   | 0.314                 |
| <b>EDSS in patients with disease duration. (&gt;10– 20 years)</b>            | 2.44 ± 1.76  | 3.74 ± 1.88   | 0.086                 |
| <b>EDSS in patients with disease duration. (&gt;20 years)</b>                | 2.70 ± 2.14  | 4.29 ± 1.63   | 0.149                 |
| No treatment   | 0.0          | 4.3           | <sup>FE</sup> p=0.600 |
| 1 <sup>st</sup> line   | 53.8         | 45.5          | 0.421                 |
| 2 <sup>nd</sup> line   | 11.5         | 31.0          | 0.040*                |
| 1 <sup>st</sup> then 2 <sup>nd</sup> (Escalated)                             | 34.6         | 19.3          | 0.072                 |

**Figure:** shows the mean EDSS scores after each duration of illness in the two groups.

## Conclusion

**We can summarise our conclusion from the current study in the following points:**

- Early disease onset does not necessitate a higher relapse rate when including the full spectrum of POMS variants into consideration and following the patients for a longer interval.
- Median times to reach advanced EDSS scores and secondary progression were longer in POMS than in AOMS.
- Most of our POMS group were started on first-line DMT compared to of AOMS patients. Nonetheless, POMS patients had on average more relapses on the first line and were escalated to second-line DMTs compared to adults.
- POMS patients who had infratentorial patches in the initial MRI significantly had a higher EDSS score than patients who did not.
- IgG index had a significant and positive correlation to the current EDSS score and the rate of EDSS progression in POMS.
